GENERALIZED CAUCHY IDENTITIES, TREES AND MULTIDIMENSIONAL BROWNIAN MOTIONS. PART II: COMBINATORIAL DIFFERENTIAL CALCULUS

ARTUR JEŻ AND PIOTR ŚNIADY

ABSTRACT. We present an analogue of the differential calculus in which the role of polynomials is played by certain ordered sets and trees. Our combinatorial calculus has all nice features of the usual calculus and has an advantage that the elements of the considered ordered sets might carry some additional information. In this way an analytic proof of generalized Cauchy identities from the previous work of the second author can be directly reformulated in our new language of the combinatorial calculus; furthermore the additional information carried by vertices determines uniquely the bijections presented in Part I of this series.

1. INTRODUCTION

1.1. **Analytic proof of generalized Cauchy identities.** The usual Cauchy identity states that for each nonnegative integer k

$$2^{2k} = \sum_{p+q=k} \binom{2p}{p}\binom{2q}{q}, \tag{1}$$

where the sum runs over nonnegative integers p, q. It is a particular case (for $n = 2$) of generalized Cauchy identities (introduced as a conjecture by Dykema and Haagerup [DH04a]) which state that if $k, n \geq 1$ are integers then

$$n^{nk} = \text{(number of certain orders on some oriented trees)}, \tag{2}$$

where the explicit form of the right-hand side will be recalled later on. For more on the history of these identities and their applications in theory of operator algebras [Aag04, AH04, DH04a, DH04b, DY03, DJS05] we refer to [Śni06].

The main idea of the first proof [Śni03] of the generalized Cauchy identities was to associate a polynomial of a single variable to every oriented tree contributing to the right-hand side of (2). These polynomials for different values of n turned out to be related by a simple differential equation and for this reason can be regarded as generalizations of Abel polynomials. These recursive formulas allowed to express the number of combinatorial objects

contributing to the right-hand side of (2) as a certain iterated integral and then to find explicitly their cardinality.

1.2. **How to convert an analytic proof into a bijection? Combinatorial calculus.** It would be very tempting to find a direct bijection between the orders on the trees contributing to the right-hand side of (2) and some simple set with the cardinality n^{nk}. Furthermore, as we pointed out in the introduction to the Part I of this series [Śni06], such a bijection could be used to extract some non-trivial information about multidimensional Brownian motions and, in particular, to find a multidimensional analogue of the arc-sine law.

Our idea in looking for such bijective proofs was the following: maybe it would be possible to extract the desired bijection directly from the analytic proof that we had? In the rest of this article we will present the details of this program. In general, a map from trees into polynomials of one variable is not invertible, i.e. usually it is not possible to extract the original tree from the corresponding polynomial, therefore we should find an analytic proof of the generalized Cauchy identities which instead of the differential and integral calculus on polynomials uses a differential and integral calculus on richer combinatorial structures.

In this article we present an analogue of the differential calculus of one variable in which the role of polynomials is played by certain ordered sets and trees. In this way an analytic proof of the generalized Cauchy identities [Śni03] can be directly reformulated in our new language. Furthermore, the additional information carried by the vertices of the graphs can be used to determine the required bijection uniquely.

This bijection was already presented in the part I of this series [Śni06] in a relatively compact algorithmic way. A great disadvantage of that approach was that it is by no means clear how the bijection from [Śni06] was invented and if it could be generalized to some other situations. Therefore the main contribution of the current article is not the bijection itself but providing a general setup which guides finding such a bijection. We also hope that our combinatorial calculus will be useful in converting analytic proofs of some other identities into bijections.

1.3. **Overview of this article.** This article is organized as follows: in Section 2 we recall the polynomials of graphs used in [Śni03] to prove its main theorem. In Section 3 we refine the ideas of polynomials to much richer combinatorial objects and describe their main properties, which are analogs of the usual laws of calculus for polynomials. In Section 4 we recall the quotient trees, the objects that were studied in [Śni03, Śni06]. In Section 5

FIGURE 1. Example of an oriented tree. The decorated vertex corresponds to the root r.

we use combinatorial calculus to construct in a conceptual way the bijection from [Śni06]. In Section 6 we construct explicitly a certain bijection f which plays a crucial role in our construction.

2. COMBINATORIAL CALCULUS: TOY EXAMPLE

In this section we present an alternative description of the usual differential calculus of a single variable. It will serve us as a toy example after which we shall model our general case.

2.1. **Oriented graphs.** By an *oriented graph* we denote a graph in which every edge is oriented. We denote an edge from vertex a to a vertex b by (a, b) and write $a \succ b$ if an edge (a, b) exists. We say that an oriented graph is *acyclic* if there is no closed loop of the form $a_1 \prec a_2 \prec \cdots \prec a_n \prec a_1$. In the following all considered oriented graphs will be assumed to be acyclic, for such graphs the relation $\prec$ can be extended to a partial order which will be denoted by the same symbol. In other words: $a \prec b$ if and only if there is a directed path from b to a. An example is presented on Fig. 1—we can see that $a \succ r$, $c \succ b \succ r$ and there is no relation between a and b or a and c. In order to avoid ambiguities we will sometimes write $\prec_G$ in order to make the dependence on the graph G explicit.

By a *rooted graph* we denote a graph with a distinguished vertex, called the *root*, denoted by r. The Reader may restrict attention to the case when the graph G is a rooted *tree* since this is the case which we consider in this article.

2.2. **Polynomial associated to a graph.** Let G be an oriented graph with a root r and the set of the vertices V. We say that a function $f : V \to [0, 1]$ is compatible with the graph G if for all pairs of vertices a, b such that $a \prec b$ we also have $f(a) < f(b)$.

Let us fix some numbering of non-root vertices. For any fixed $x \in [0, 1]$ the set

$$Z_G(x) = \big\{ f : V \to [0, 1] \text{ such that } f \text{ is compatible with } G \text{ and } f(r) = x \big\}$$

can be identified with a subset of a hypercube $[0, 1]^{|V|-1}$ and hence its volume

$$\mathbb{E}_G(x) := \operatorname{vol} Z_G(x) \tag{3}$$

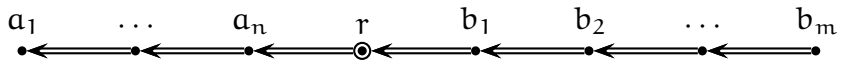

FIGURE 2. Tree for which the partial order $\prec$ is a total order. It is a (n, m)-chain.

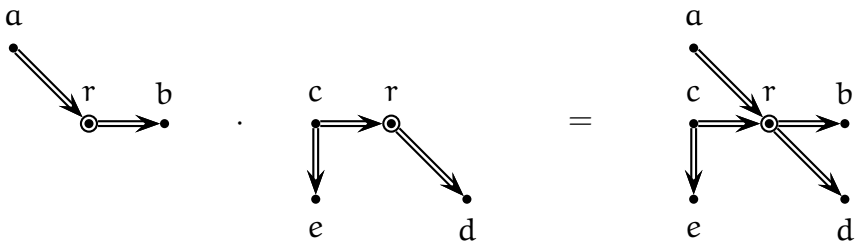

FIGURE 3. Product of trees.

makes sense. It turns out that $\mathbb{E}_G$ is a polynomial of degree $|V| - 1$. These polynomials were the key analytic tool in the proof of generalized Cauchy identities [Śni03]. For technical reasons it is useful to define $\mathbb{E}$ also for formal linear combinations of graphs

$$\mathbb{E}_{\sum_i k_i G_i} := \sum_i k_i \, \mathbb{E}_{G_i},$$

where $k_i \in \mathbb{Z}$ and G_i is a graph and where i takes a finite number of values.

2.3. **Linear orders.** In the following we will pay special attention to the case when $G = T$ is a tree for which the corresponding partial order $\prec$ is a total order. Such a tree must have a form depicted on Fig. 2 for some integers $n, m \geq 0$. We use a name (n, m)-chain, or $T_{n,m}$ to denote such a tree. In this case the set $Z_T(x)$ can be viewed as

$$\{(a_1, \ldots, a_n, b_1, \ldots, b_m) : \\ 0 < a_1 < \cdots < a_n < x < b_1 < \cdots < b_m < 1\} \subseteq [0,1]^{n+m}. \tag{4}$$

We also use a special name for the associated polynomials:

$$\mathbb{E}_{n,m} = \frac{x^n}{n!} \frac{(1-x)^m}{m!}. \tag{5}$$

2.4. **Products of graphs.** Let G_1, G_2 be oriented, rooted graphs. For simplicity we shall assume that the sets of the non-root vertices of these graphs are disjoint. We define a product $G_1 \cdot G_2$ to be the union $G_1 \cup G_2$ in which the roots of G_1 and G_2 are identified. An example of a product of trees is presented on Fig. 3.

We leave it as a simple exercise that

$$\mathbb{E}_{G_1 \cdot G_2}(x) = \mathbb{E}_{G_1}(x) \, \mathbb{E}_{G_2}(x). \tag{6}$$

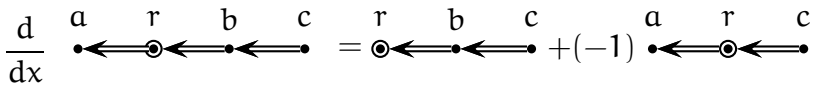

FIGURE 4. Example of derivative of a tree.

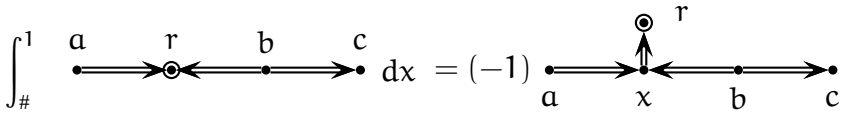

FIGURE 5. Example of antiderivative.

2.5. **Derivatives of graphs.** Let G be an oriented rooted graph. We define $\frac{d}{dx}G$ to be a formal linear combination of the graphs given by

$$\frac{d}{dx}G = \sum_e (-1)^e G_{(e)}, \tag{7}$$

where $G_{(e)}$ denotes the graph G with the edge e contracted, $(-1)^e = -1$ if the arrow on e points towards the root and $(-1)^e = 1$ otherwise and the sum runs over all edges e attached to the root. Example is given on Fig. 4.

One can show that

$$\mathbb{E}_{\frac{d}{dx}G}(x) = \frac{d}{dx}\mathbb{E}_G(x), \tag{8}$$

where the derivative on the right-hand side is the usual derivative of polynomials.

2.6. **Value in 0 and 1.** We focus on the case when T is a chain. In this case $\mathbb{E}_T = \mathbb{E}_{n,m} = \frac{x^n}{n!}\frac{(1-x)^m}{m!}$. The Reader should check that

$$\mathbb{E}_{n,m}(1) = \begin{cases} \frac{1}{n!} & \text{if } m = 0, \\ 0 & \text{otherwise,} \end{cases} = \begin{cases} \sum_{i=0}^{n} \mathbb{E}_{i,n-i}(x) & \text{if } m = 0, \\ 0 & \text{otherwise.} \end{cases} \tag{9}$$

The number $\frac{1}{n!}$ in the middle was written as a linear combination of polynomials on the right-hand side hence we can treat (9) as a definition of an usual embedding $\mathbb{R} \ni a \mapsto a + 0x + 0x^2 + \cdots \in \mathbb{R}[x]$.

We leave it as an exercise to check that analogous result holds true in the case of the value in 0.

2.7. **Integrals of graphs.** We use the notation that $\int_\#^1 f\,dx$ is a function g such that $g(y) = \int_y^1 f(x)\,dx$. We define the corresponding integral for graphs: for a graph G we look for G' (which is a formal linear combination of graphs) such that $\frac{d}{dx}\mathbb{E}_{G'} = (-1)\cdot\mathbb{E}_G$ and $\mathbb{E}_{G'}(1) = 0$. One—particularly elegant—way of constructing such G' is to rename the old root of G into an

ordinary vertex x and to add a new root r; then to connect r with x with an arrow pointing at r; we denote the resulting graph by $\tilde{G}$, see Fig. 5. Then

$$\int_{\#}^{1} G \, dx := (-1) \cdot \tilde{G}$$

has the required properties.

We leave it as an exercise to define the integral $\int_0^{\#} G \, dx$.

2.8. **Extensions of a partial order.** Let G be an oriented graph with the vertex set V and let $\prec$ be the corresponding partial order on the set of the vertices. We say that a total order $<$ is compatible with G if $a \prec b$ implies $a < b$. In this article we are interested in a problem initiated by Dykema and Haagerup [DH04a] of studying the set of all total orders $<$ compatible with a given tree $G = T$.

With a small abuse of notation we shall sometimes identify a tree equipped with a total order $(T, <)$ with a chain depicted on Fig. 2 with the same vertex set V and with the order of the vertices $\prec$ specified by $<$. Hence

$$\mathbb{E}_{(T,<)} = \mathbb{E}_{n,m} = \frac{x^n}{n!} \frac{(1-x)^m}{m!} \tag{10}$$

makes sense, where n (respectively, m) denotes the number of the vertices of T smaller (respectively, bigger) with respect to $<$ than the root r.

One can easily check that

$$\mathbb{E}_T = \sum_{<} \mathbb{E}_{(T,<)}, \tag{11}$$

where the sum runs over all total orders $<$ compatible with a tree T.

2.9. **Towards the combinatorial calculus.** Any polynomial can be written as a linear combination of the polynomials of the form $\mathbb{E}_G$ where G is a directed graph. It follows that many operations on polynomials (such as multiplication, differentiation, integration, taking the value in 0 or 1) can be equivalently performed on the corresponding graphs. Notice, however, that one polynomial can be represented in many ways as a linear combination of graphs.

Let a directed graph G with a vertex set V be given. Since the polynomials $\{\mathbb{E}_{n,m} : n + m = |V| - 1\}$ defined in (5) form a basis of the space of the polynomials of degree at most $|V| - 1$ hence the polynomial $\mathbb{E}_T(x)$ gives us the information about the number of the total orders $<$ compatible with T and such that the number of the vertices smaller than the root r is specified. Unfortunately, more detailed information about the order of the vertices with respect to all possible values of $<$ is lost in $\mathbb{E}_T$ and for this

reason in Section 3 we shall replace the ring $\mathbb{R}[x]$ of the polynomials by a richer combinatorial structure.

3. Combinatorial Differential Calculus

In this section we are going to furnish the objects which appeared in Section 2 with a richer combinatorial structure. Major changes will concern the ring of scalars $\mathbb{R}$ in Section 3.2 and the ring of polynomials $\mathbb{R}[x]$ in Section 3.3. In Section 3.9 we will revisit the toy example from Section 2 and discuss the heuristic meaning of newly introduced algebraic structures $\mathcal{R}$ and $\mathcal{R}[x]$.

3.1. **Graphs.** Let L be a fixed set of labels. By $\mathcal{G}$ we denote the set of labeled, directed, acyclic rooted graphs G such that the root of G is labeled with $r \notin L$ and all other vertices of G are labeled with different elements of L. By $\mathcal{T}$ we denote the subset of $\mathcal{G}$ consisting of directed trees. We define $\mathbb{Z}(\mathcal{G})$ as the set of formal linear combinations (with integer coefficients) of elements from $\mathcal{G}$. For graphs in $\mathcal{G}$ we define multiplication in the same way as in Section 2.4. By linearity it extends to $\mathbb{Z}(\mathcal{G})$.

Remark. In order to avoid technical difficulties we shall always assume that the vertices of any two graphs involved in any operations considered in the following have different labels, except for the root, nevertheless this assumption is not essential.

3.2. **Scalars.** By $\mathcal{R}_0$ we denote the set of all finite sequences with (all different) elements from L. We define $\mathcal{R}$ to be the set of formal linear combinations (with integer coefficients) of $\mathcal{R}_0$. This notation was so chosen because $\mathcal{R}$ is an analogue of the set of scalars $\mathbb{R}$.

We identify a finite sequence $(a_1, \ldots, a_n)$ with an ordered multiset $A = \{a_1, \ldots, a_n\}$ where $a_1 < \cdots < a_n$, also written as $(A, <)$. We can also represent it as a graph with vertices $a_1, \ldots, a_n$ with oriented edges $(a_n, a_{n-1}), \ldots, (a_2, a_1)$.

Let $A, B \in \mathcal{R}_0$ be sequences of length m, n, respectively. We define $AB \in \mathcal{R}$ to be the formal linear combination of $\binom{m+n}{m}$ sequences obtained by intertwining the sequences A and B. For example:

$$(a,b)(c,d) = (a,b,c,d) + (a,c,b,d) + (a,c,d,b) + (c,a,b,d) + (c,a,d,b) + (c,d,a,b). \tag{12}$$

By linearity this allows us to define the product of two elements of $\mathcal{R}$. This multiplication is commutative and associative and it has a unit equal to the empty sequence $\emptyset$.

FIGURE 6. Graphical representation of $(a, b) \otimes (c, d)$.

3.3. **Polynomials and extensions of partial orders.** For $A = (a_1, \dots, a_n), B = (b_1, \dots, b_m) \in \mathcal{R}_0$ we define

$$A \otimes B = (a_1, \dots, a_n, r, b_1, \dots, b_m)$$

and view this as an ordered multiset (where r is some distinguished element such that $r \notin L$), see Fig. 6.

By $\mathcal{R}[r]$ we denote the set of formal linear combinations (with integer coefficients) of the elements $A \otimes B$ where $A, B \in \mathcal{R}_0$. This notation was chosen because $\mathcal{R}[r]$ is an analogue of the algebra of polynomials $\mathbb{R}[x]$. We replaced the letter x with r in order to stress the connection with the root equipped with label r.

We equip $\mathcal{R}[r]$ with a multiplication by setting

$$(A \otimes B)(C \otimes D) := (AC) \otimes (BD).$$

This product can be described as follows: for $(A \otimes B)$ and $(C \otimes D)$ we identify the elements r appearing in each of them. The product $(A \otimes B)(C \otimes D)$ is equal to the formal linear combination of all possible linear orders on $A \cup B \cup C \cup D \cup \{r\}$ extending the orders on $(A \otimes B)$ and $(C \otimes D)$ respectively. Element $\emptyset \otimes \emptyset$ is a unit of this multiplication. This multiplication is commutative and associative.

Every totally ordered set containing r can be viewed as an element of $\mathcal{R}[r]$. For a directed graph $G \in \mathcal{G}$ with a vertex set V we define $\mathbb{E}_G \in \mathcal{R}[r]$ to be a formal linear combination of all ordered sets $(V, <) \in \mathcal{R}[r]$, where the sum runs over all total orders $<$ compatible with G.

It is easy to check that the following analogue of (6) holds true.

Proposition 1. *For all* $G_1, G_2 \in \mathbb{Z}(\mathcal{G})$

$$\mathbb{E}_{G_1 \cdot G_2} = \mathbb{E}_{G_1} \cdot \mathbb{E}_{G_2},$$

where the multiplication on the left-hand side denotes the product of trees and the multiplication on the right-hand side denotes the product in $\mathcal{R}[r]$.

3.4. **Derivative.** In analogy to (7) for $a \in L$ and $G \in \mathcal{G}$ we define the a-derivative by

$$\frac{\partial}{\partial a} G = G_{(r,a)} - G_{(a,r)}, \tag{13}$$

where G_e denotes the graph G in which the edge e was contracted and non-root label removed or 0 if edge e does not exist. Notice that for simplicity we assumed that the labels of G are all different therefore there is at most

one edge which could be contracted in $G_{(r,a)}$, respectively $G_{(a,r)}$; in order to cover the general situation one would have to consider the formal linear combination of the graphs, each obtained from G by contracting one edge of the form (r, a), respectively (a, r).

For any $A = (a_1, \dots, a_n), B = (b_1, \dots, b_m) \in \mathcal{R}_0$ we may treat $A \otimes B \in \mathcal{R}[r]$ as an element of $\mathcal{G}$. In this way for any $X \in \mathcal{R}[r]$ its derivative $\frac{\partial}{\partial a}X$ is well-defined and is an element of $\mathcal{R}[r]$. This derivative is given explicitly by

$$\frac{\partial}{\partial a}\big(A \otimes B\big) = [a_m = a]\,(a_1, \dots, a_{m-1}) \otimes B - [b_1 = a]\,A \otimes (b_2, \dots, b_n).$$

The following result is an analogue of (8).

Proposition 2. *For every graph* $G \in \mathcal{G}$ *and* $a \in L$

$$\mathbb{E}\left(\frac{\partial}{\partial a}G\right) = \frac{\partial}{\partial a}\mathbb{E}(G). \tag{14}$$

Proof. This proof is the only place of this paper when we consider graphs which are not trees or forests. We will use the backward induction with respect to the number of edges of G.

Firstly, let us consider the case when G is a full graph (every pair of vertices is connected by an oriented edge) and acyclic. Then $\mathbb{E}(G)$ consists of exactly one total order on the vertices of G hence there are at most two summands which contribute to the right-hand side of (14). One can easily check that there are at most two edges e of G adjacent to the root for which the contracted graph $G_{(e)}$ is acyclic and that they correspond to the summands on the right-hand side of (14) which finishes the proof.

If G is not a full graph we may chose a pair b, c of vertices not connected by G. Let G_1 (respectively, G_2) denote the graph G augmented by an edge pointing from b to c (respectively, in the opposite direction). It is straightforward to show that

$$\mathbb{E}\left(\frac{\partial}{\partial a}G\right) = \mathbb{E}\left(\frac{\partial}{\partial a}G_1\right) + \mathbb{E}\left(\frac{\partial}{\partial a}G_2\right)$$

and

$$\frac{\partial}{\partial a}\mathbb{E}(G) = \frac{\partial}{\partial a}\mathbb{E}(G_1) + \frac{\partial}{\partial a}\mathbb{E}(G_2);$$

notice that it might happen that G_i is not acyclic, in this case $\mathbb{E}(G_i) = 0$. The inductive hypothesis can be applied to G_1 and G_2 which finishes the proof. □

The derivative defined above has analogous properties to the usual derivative. For example, it fulfills Leibniz rule which we leave as a simple exercise.

Proposition 3 (Leibniz rule)**.** *For every* $X_1, X_2 \in \mathcal{R}[r]$ *and* $a \in L$ *we have*

$$\frac{\partial}{\partial a}(X_1X_2) = \left(\frac{\partial}{\partial a}X_1\right)X_2 + X_1\left(\frac{\partial}{\partial a}X_2\right).$$

For every $G_1, G_2 \in \mathcal{G}$ *and* $a \in L$ *we have*

$$\frac{\partial}{\partial a}(G_1G_2) = \left(\frac{\partial}{\partial a}G_1\right)G_2 + G_1\left(\frac{\partial}{\partial a}G_2\right).$$

3.5. **Embedding of $\mathcal{R}$ into $\mathcal{R}[r]$.** In analogy to embedding (9) of $\mathbb{R}$ into $\mathbb{R}[x]$ we define embedding $\iota : \mathcal{R} \to \mathcal{R}[r]$ given by

$$\iota(a_1, \dots, a_n) = \sum_{0 \le k \le n} (a_1, \dots, a_k) \otimes (a_{k+1}, \dots, a_n) \tag{15}$$

and which can be alternatively described as follows: to an oriented graph associated to a chain $(a_1, \dots, a_n)$ we add an additional vertex r, not connected with any other vertices; the resulting graph we denote by G. Then the right-hand side of (15) is equal to $\mathbb{E}_G$.

The Reader may recognize some similarities of the above definition of ι to the definition of embedding (9) of $\mathbb{E}_{n,m}(1)$ into $\mathbb{R}[x]$.

Proposition 4. *For each* $X \in \mathcal{R}[r]$ *the element* $\iota(X)$ *is a* constant function *in a sense that for any* $a \in L$

$$\frac{\partial}{\partial a}\iota(X) = 0.$$

3.6. **Value in 0 and 1.** As we have seen in Section 2.6 the value in 1 for chains has some nice properties. We define for $A \otimes B \in \mathcal{R}$

$$(A \otimes B)(1) = [B = \emptyset]\ \ \iota(A) \in \mathcal{R}[r]. \tag{16}$$

Note that if the root of G has at least one successor then $\big(\mathbb{E}(G)\big)(1) = 0$.

Similarly, we define

$$(A \otimes B)(0) = [A = \emptyset]\ \ \iota(B) \in \mathcal{R}[r].$$

3.7. **Integrals.** We have already defined integrals for graphs in Section 2.7; we shall keep this definition with the only change that in the integral of the form $\int_\#^1 G\ da$ the old root of the graph G will given a label a. We also

define an integral for $\mathcal{R}[r]$, namely for $a \in L$ we define

$$\int_{\#}^{1} (a_1, \dots, a_m) \otimes (b_1, \dots, b_n)\, da = (-1) \sum_{0 \le k \le m} (a_1, \dots, a_k) \otimes (a_{k+1}, \dots, a_m, a, b_1, \dots, b_n) \in \mathcal{R}[r]. \tag{17}$$

The above two integrals (one on $\mathcal{G}$ and one on $\mathcal{R}[r]$) are compatible with each other since

$$\mathbb{E}\left(\int_{\#}^{1} (a_1, \dots, a_m) \otimes (b_1, \dots, b_n)\, da\right) = \int_{\#}^{1} (a_1, \dots, a_m) \otimes (b_1, \dots, b_n)\, da,$$

where on the left-hand side we identify $(a_1, \dots, a_m) \otimes (b_1, \dots, b_n)$ with an element of $\mathcal{G}$ and on the right-hand we treat it as an element of $\mathcal{R}[r]$.

Similarly, we define

$$\int_{0}^{\#} (a_1, \dots, a_m) \otimes (b_1, \dots, b_n)\, da = \sum_{0 \le k \le m} (a_1, \dots, a_m, a, b_1, \dots, b_k) \otimes (b_{k+1}, \dots, b_n) \in \mathcal{R}[r]. \tag{18}$$

3.8. **Basic properties of integrals.**

Theorem 5 (Fundamental theorem of calculus)**.** *For any* $F \in \mathcal{R}[r]$ *we have*

$$F = \iota\big[F(0)\big] + \sum_{a \in L} \int_{0}^{\#} \left(\frac{\partial}{\partial a} F\right)\, da, \tag{19}$$

where the integral should be understood as the integral in $\mathcal{R}[r]$.

Proof. Since the integral and the derivative are linear it is sufficient to prove this equality for $F = A \otimes B = (a_1, \dots, a_m) \otimes (b_1, \dots, b_n)$. Let us calculate the right-hand side in the case when $n, m \ge 1$. We notice, that although the

sum is over all $a \in L$, only a_m and b_1 matter:

$$\iota\big[F(0)\big] + \sum_{a\in L} \int_0^{\#} \left(\frac{\partial}{\partial a} F\right)\, da =$$

$$0 + \int_0^{\#} (a_1, \dots, a_{m-1}) \otimes B \; da_m - \int_0^{\#} A \otimes (b_2, \dots, b_n) \; db_1 =$$

$$\sum_{0\le k\le n} (a_1, \dots a_{m-1}, a_m, b_1, \dots, b_k) \otimes (b_{k+1}, \dots, b_n) -$$

$$\sum_{0\le k\le n-1} (a_1, \dots, a_m, b_1, b_2, \dots, b_{k+1}) \otimes (b_{k+2}, \dots b_n) =$$

$$(a_1, \dots, a_m) \otimes (b_1, \dots, b_n).$$

The proof in the case when n or m is equal to 0 requires only minor modifications. □

Corollary 6. *Let* $X, Y \in \mathcal{R}[r]$ *and* $a \in L$. *If* $Y(0) = 0$, $\frac{\partial}{\partial a} Y = X$ *and* $\frac{\partial}{\partial a'} Y = 0$ *holds true for every* $a' \neq a$ *then*

$$Y = \int_0^{\#} X \; da.$$

The following proposition shows that the integral is linear with respect to multiplication by scalars.

Proposition 7. *For every* $C \in \mathcal{R}$ *and* $D \in \mathcal{R}[r]$ *and* $a \in L$ *we have*

$$\iota(C) \cdot \int_0^{\#} D \; da = \int_0^{\#} \iota(C) \cdot D \; da \in \mathcal{R}[r].$$

Proof. We use Corollary 6 for $Y = \iota(C) \cdot \int_0^{\#} D \; da$ and $X = \iota(C) \cdot D$. □

Theorem 8 (Taylor expansion)**.** *For any* $F \in \mathcal{R}[r]$ *we have*

$$F = \sum_{\substack{k\ge 0 \\ a_1,\dots,a_k \in L}} \iota \left[\left(\frac{\partial}{\partial a_1} \cdots \frac{\partial}{\partial a_k} F \right)(0) \right] \cdot ((a_1, \dots, a_k) \otimes \emptyset) \tag{20}$$

and

$$F = \sum_{\substack{k\ge 0 \\ a_1,\dots,a_k \in L}} (-1)^k \, \iota \left[\left(\frac{\partial}{\partial a_1} \cdots \frac{\partial}{\partial a_k} F \right)(1) \right] \cdot (\emptyset \otimes (a_k, a_{k-1}, \dots, a_1)) \,. \tag{21}$$

Proof. In (19) we can further expand $\frac{\partial}{\partial a} F$ using the same rule. But F has a finite number of points and every $\frac{\partial}{\partial a}$ reduces the number of points in

F, hence the expansion will end after some finite number of steps and we obtain:

$$F = \sum_{\substack{k\geq 0\\ a_1,\ldots,a_k\in L}} \int_0^{\#}\left[\cdots\left[\int_0^{\#}\iota\left[\left(\frac{\partial}{\partial a_1}\cdots\frac{\partial}{\partial a_k}F\right)(0)\right]\,da_1\right]\cdots\right]da_k =$$

$$\sum_{\substack{k\geq 0\\ a_1,\ldots,a_k\in L}} \iota\left[\left(\frac{\partial}{\partial a_1}\cdots\frac{\partial}{\partial a_k}F\right)(0)\right]\,\int_0^{\#}\left[\cdots\left[\int_0^{\#}\emptyset\otimes\emptyset\,da_1\right]\cdots\right]da_k =$$

$$\sum_{\substack{k\geq 0\\ a_1,\ldots,a_k\in L}} \iota\left[\left(\frac{\partial}{\partial a_1}\cdots\frac{\partial}{\partial a_k}F\right)(0)\right]\,((a_1,\ldots,a_k)\otimes\emptyset)\,,$$

where in the second equality we use Proposition 7 since $\iota\left[\frac{\partial}{\partial a_1}\cdots\frac{\partial}{\partial a_k}F(0)\right]$ is a scalar and hence we are allowed to move it outside the integral.

The other equation can be proved in an analogous way. □

3.9. **Toy example revisited.** It is time to have a look on the definitions introduced in this section and to give them heuristic meaning.

As we mentioned in Section 2.9 the polynomial $\mathbb{E}_G \in \mathbb{R}[x]$ fulfills (11) hence gives some partial information on the extensions of the partial order on the vertices of G to total orders. Similarly, the element $\mathbb{E}_G \in \mathcal{R}[r]$ gives (complete) information on such extensions; for this reason we regard $\mathcal{R}[r]$ as a generalization of $\mathbb{R}[x]$.

Operations $f \mapsto f(0)$ and $f \mapsto f(1)$ map polynomials $\mathbb{R}[x]$ to scalars $\mathbb{R}$; similarly operations $F \mapsto F(0)$ and $F \mapsto F(1)$ map $\mathcal{R}[r]$ to $\mathcal{R}$, therefore we regard $\mathcal{R}$ as an analogue of the set of scalars $\mathbb{R}$.

The usual Taylor expansion for a polynomial f says that

$$f(x) = \sum_{k\geq 0}\left[\frac{d^k}{dx^k}f(0)\right]\frac{x^k}{k!}$$

and

$$f(x) = \sum_{k\geq 0}(-1)^k\left[\frac{d^k}{dx^k}f(1)\right]\frac{(1-x)^k}{k!};$$

clearly each summand on the right-hand sides involves a product of a scalar $\frac{d^k}{dx^k}f(0) \in \mathbb{R}$ with a polynomial $\frac{x^k}{k!} \in \mathbb{R}[x]$, respectively of a scalar $(-1)^k\frac{d^k}{dx^k}f(1) \in \mathbb{R}$ with a polynomial $\frac{(1-x)^k}{k!} \in \mathbb{R}[x]$. In order to define such a product we identify $\mathbb{R}$ with the set of constant polynomials in $\mathbb{R}[x]$. Similarly, in the Taylor expansion for chains (20) and (21) we needed the map ι to identify $\mathcal{R}$ as a subset of $\mathcal{R}[r]$. In fact, every derivative $\frac{\partial}{\partial a}$ vanishes on

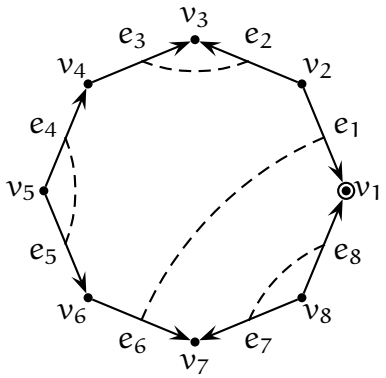

FIGURE 7. Graph G_ϵ corresponding to sequence $\epsilon = (+1,-1,+1,+1,-1,-1,+1,-1)$. The dashed lines represent a pairing $\sigma = \big\{\{1,6\},\{2,3\},\{4,5\},\{7,8\}\}\big\}$.

the image of ι therefore we can think that ι maps $\mathcal{R}$ into *constant* elements of $\mathcal{R}[r]$.

The main difference between calculus on $\mathbb{R}[x]$ and $\mathcal{R}[r]$ is the multitude of derivatives $\frac{\partial}{\partial a}$ and integrals $\int_0^{\#}\cdot\, da$, $\int_{\#}^1\cdot\, da$ indexed by $a \in L$. Each of these derivatives and integrals is sensitive to only one label $a \in L$; despite this multitude we regard our combinatorial calculus as a generalization of the calculus in *one* variable (as opposite to calculus in several variables) because the total orders which we consider have an inherent one-dimensional structure.

4. QUOTIENT GRAPHS AND QUOTIENT TREES

The machinery of combinatorial calculus presented in Section 3 was build for the sole purpose of giving a better understanding of the analytic proof of generalized Cauchy identities from [Śni03]. In this section we introduce the underlying combinatorial structure—quotient graphs and trees.

4.1. **Quotient graphs and quotient trees.** We recall now the construction of Dykema and Haagerup [DH04a]. For an integer $k \geq 1$ let G be an oriented k–gon graph with consecutive vertices $v_1,\dots,v_k$ and edges $e_1,\dots,e_k$ (edge e_i connects vertices v_i and v_{i+1}). The vertex v_1 is distinguished, see Fig. 7. We encode the information about the orientations of the edges in a sequence $\epsilon(1),\dots,\epsilon(k)$ where $\epsilon(i) = +1$ if the arrow points from v_{i+1} to v_i and $\epsilon(i) = -1$ if the arrow points from v_i to v_{i+1}. The graph G is uniquely determined by the sequence ϵ and sometimes we will explicitly state this dependence by using the notation G_ϵ.

Let $\sigma = \big\{\{i_1,j_1\},\dots,\{i_{k/2},j_{k/2}\}\big\}$ be a pairing of the set $\{1,\dots,k\}$, i.e. pairs $\{i_m,j_m\}$ are disjoint and their union is equal to $\{1,\dots,k\}$. We say that

σ is compatible with ϵ if

$$\epsilon(i) + \epsilon(j) = 0 \qquad \text{for every } \{i,j\} \in \sigma. \tag{22}$$

It is a good idea to think that σ is a pairing between the edges of G, see Fig. 7. For each $\{i,j\} \in \sigma$ we identify (or, in other words, we glue together) the edges e_i and e_j in such a way that the vertex v_i is identified with v_{j+1} and vertex v_{i+1} is identified with v_j and we denote by T_σ the resulting quotient graph. The condition (22) implies that each edge of T_σ carries a natural orientation, inherited from each of the two edges of G it comes from.

From the following on, we consider only the case when the quotient graph T_σ is a tree. One can show [DH04a] that the latter holds if and only if the pairing σ is *non–crossing* [Kre72]; in other words it is not possible that for some $p < q < r < s$ we have $\{p,r\},\{q,s\} \in \sigma$. The name of the non–crossing pairings comes from their property that on their graphical depictions (such as Fig. 7) the lines do not cross. Let the root r of the tree T_σ be the vertex corresponding to the distinguished vertex v_1 of the graph G.

We say that a sequence $\epsilon = (\epsilon(1), \ldots, \epsilon(n))$ is *Catalan* when

$$\sum_{i=1}^{k} \epsilon(i) \geq 0 \qquad \text{for every } k \leq n \tag{23}$$

and

$$\sum_{i=1}^{n} \epsilon(i) = 0.$$

We say that ϵ is *anti-Catalan*, when $-\epsilon$ is Catalan. Note, that for a Catalan (respectively: anti-Catalan) sequence and every non-crossing pairing σ in T_σ there is no edge incident to the root and pointing from the root (respectively: towards the root). If such edge existed then some starting part of ϵ would sum up to -1, which contradicts (23).

For Catalan sequences one specific pairing will be important in the following sections, namely the *Catalan pairing*:

Lemma 9. *For a Catalan (respectively: anti-Catalan) sequence ϵ there exists a unique pairing σ such that in T_σ all edges are directed toward the root (respectively: in the opposite direction than towards the root). We call this pairing Catalan pairing.*

4.2. **Preorder.** The preorder [Sta99], denoted by $\lhd$, is defined for trees embedded on a plane. To obtain it we must traverse a tree from the root according to the following rule—always choose the left-most untraversed edge. If there is none, go up the tree. The preorder is defined by the time of

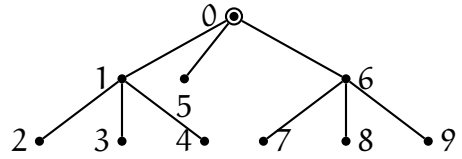

FIGURE 8. Order $\lhd$ on a rooted plane tree

the first visit in the vertex. Perhaps the illustration on Fig. 8 will be better than dwelling this formal definition.

5. HOW TO CONVERT AN ANALYTIC PROOF INTO A BIJECTION

5.1. **Formulation of the main result.** Let $T_\epsilon := \sum_\sigma T_\sigma$ be a formal linear combination of the quotient trees, where σ runs over all non-crossing partitions compatible with ϵ.

Let $l_1 \le l_2 \le \dots$ be a weakly increasing sequence of natural numbers. For each $i \ge 0$ we consider a Catalan sequence

$$\epsilon_i = \Big(\underbrace{(1)}_{l_i \text{ times}}, \underbrace{(-1)}_{l_{i-1} \text{ times}}, \dots, \underbrace{(-1)^{i-2}}_{l_2 \text{ times}}, \underbrace{(-1)^{i-1}}_{l_1 \text{ times}}, \underbrace{(-1)^{i}}_{l_1 \text{ times}}, \underbrace{(-1)^{i-1}}_{l_2 \text{ times}}, \dots, \underbrace{(-1)}_{l_i \text{ times}} \Big),$$

where for simplicity instead of $\underbrace{a, a, \dots, a}_{m \text{ times}}$ we write $\underbrace{a}_{m \text{ times}}$.

The following result was proved (in a slightly different form) in [Śni03].

Theorem 10. *For each fixed $m \ge 1$ we denote $L = l_1 + \dots + l_m$ and $\epsilon = \epsilon_m$. For any $0 < x < 1$ the value of the polynomial $\mathbb{E}\big[T_\epsilon\big] \in \mathbb{R}[x]$ is given by*

$$\begin{aligned} \mathbb{E}\big[T_\epsilon\big](x) = \operatorname{vol}\Big\{ (x_1, \dots, x_L) \in \mathbb{R}^L : \\ 0 > x_1 > x_2 > \dots > x_L > x - m \text{ and} \\ \{x_1, \dots, x_L, x - m\} \cap [-i, 0] \text{ consists of at most} \\ l_1 + \dots + l_i \text{ elements for each } 1 \le i \le m-1 \Big\}. \end{aligned} \tag{24}$$

Also

$$\begin{aligned} \int_0^1 \mathbb{E}\big[T_\epsilon\big](x)\,dx = \operatorname{vol}\Big\{ (x_1, \dots, x_L, z) \in \mathbb{R}^{L+1} : \\ 0 > x_1 > x_2 > \dots > x_L > z > -m \text{ and} \\ \{x_1, \dots, x_L, z\} \cap [-i, 0] \text{ consists of at most} \\ l_1 + \dots + l_i \text{ elements for each } 1 \le i \le m-1 \Big\}. \end{aligned} \tag{25}$$

Let $c_1, \ldots, c_m$ be different colors. We consider a function which maps $[-m, 0)$ into $[0,1] \times \{c_1, \ldots, c_m\}$ given by

$$f(x) = \begin{cases} (\lceil x \rceil - x, c_{-\lfloor x \rfloor}) & \text{if } (-m - \lfloor x \rfloor) \text{ is odd,} \\ (x - \lfloor x \rfloor, c_{-\lfloor x \rfloor}) & \text{if } (-m - \lfloor x \rfloor) \text{ is even.} \end{cases}$$

Notice that the graph of the first coordinate is a zig-zag.

In the following we shall view $(x, c_i) \in [0,1] \times \{c_1, \ldots, c_m\}$ as number x decorated with a color c_i; in this way the map

$$(x_1, \ldots, x_L, z) \mapsto \big\{ f(x_1), \ldots, f(x_L), f(z) \big\}$$

provides a bijection between the tuples $(x_1, \ldots, x_L, z)$ which contribute to the set on the right-hand side of (25) and sets consisting of $L+1$ elements, each element being a number from the interval $[0,1]$ and decorated with a color from the set $\{c_1, \ldots, c_m\}$ with an additional property that for each $1 \le i < m$ at most $l_1 + \cdots + l_i$ elements are decorated with colors from the set $\{c_1, \ldots, c_i\}$ (notice that this map is not well-defined or is not a bijection only on a set of measure zero with respect to the Lebesgue measure). The element $f(z)$ will play a special role, we declare it the root. Therefore Theorem 10 suggests that the following stronger result could be true.

Theorem 11 (The main result)**.** *We denote $\epsilon = \epsilon_m$. There is an explicit way of decorating the vertices of all ordered trees $(T, <)$ contributing to $\mathbb{E}[T_\epsilon]$ with colors $c_1, \ldots, c_m$ in such a way that $\mathbb{E}(T_\epsilon) \in \mathcal{R}[r]$ is equal to*

$$S = \sum \iota\big[(\underbrace{c_1, \ldots, c_1}_{s_1 \text{ times}})\big] \cdots \iota\big[(\underbrace{c_{m-1}, \ldots, c_{m-1}}_{s_{m-1} \text{ times}})\big] \cdot \big[\emptyset \otimes (\underbrace{c_m, \ldots, c_m}_{s_m \text{ times}})\big], \tag{26}$$

where the sum runs over tuples of non-negative integers $(s_1, \ldots, s_m)$ with a property that $s_1 + \cdots + s_m = l_1 + \cdots + l_m$ and $s_1 + \cdots + s_i \le l_1 + \cdots + l_i$ for $1 \le i \le m-1$.

The remaining part of the article will be devoted to the proof of the above theorem.

Corollary 12. *There is an explicit bijection between*

- *the set of pairs $(\sigma, <)$, where σ is a pairing compatible with ϵ and $<$ is a total order on the vertices of T_σ extending $\prec$;*
- *the set of sequences $(a_1, \ldots, a_L)$ such that $a_1, \ldots, a_L \in \{1, \ldots, m\}$ and for each $1 \le i \le m-1$ at most $l_1 + \cdots + l_i$ elements of the sequence (a_n) belong to the set $\{1, \ldots, i\}$.*

Proof. We color each tree $(T, <)$ contributing to $\mathbb{E}[T_\epsilon]$ as in Theorem 11; additionally we paint the root with the color c_m. To each such a colored tree with a linear order $<$ of the vertices we associate the sequence of the colors

enumerated according to the order $<$; furthermore each color c_i is replaced by its number i. Theorem 11 shows that it is the required bijection. □

5.2. **Idea of the proof.** We are going to prove Theorem 11 by induction with respect to m. Let $\epsilon' = -\epsilon_{m-1}$; by reversing the order of the linear orders it follows that the inductive hypothesis is equivalent to the following statement.

Inductive hypothesis 13. *There is an explicit way of decorating the vertices of all ordered trees $(T, <)$ contributing to $\mathbb{E}[T_{\epsilon'}]$ with colors $c_1, \dots, c_{m-1}$ in such a way that $\mathbb{E}(T_{\epsilon'}) \in \mathcal{R}[r]$ is equal to*

(27)
$$S' = \sum \iota\Big[(\underbrace{c_1, \dots, c_1}_{s_1 \text{ times}})\Big] \cdots \iota\Big[(\underbrace{c_{m-2}, \dots, c_{m-2}}_{s_{m-2} \text{ times}})\Big] \cdot \Big[(\underbrace{c_{m-1}, \dots, c_{m-1}}_{s_{m-1} \text{ times}}) \otimes \emptyset\Big],$$

where the sum runs over $(s_1, \dots, s_{m-1})$ with a property that $s_1 + \cdots + s_{m-1} = l_1 + \cdots + l_{m-1}$ and $s_1 + \cdots + s_i \le l_1 + \cdots + l_i$ for $1 \le i \le m-2$.

A straightforward calculation based on Proposition 3 and Proposition 4 shows that S given by (26) fulfills

(28)
$$\left[\frac{\partial}{\partial x_j} \cdots \frac{\partial}{\partial x_1} S\right](1) = 0 \qquad \text{if } (x_1, \dots, x_j) \neq (c_m, \cdots, c_m),$$

(29)
$$\Big[\underbrace{\frac{\partial}{\partial c_m} \cdots \frac{\partial}{\partial c_m}}_{j \text{ times}} S\Big](1) = \begin{cases} 0 & \text{if } j < l_m, \\ (-1)^j \Big[\underbrace{\dfrac{\partial}{\partial c_{m-1}} \cdots \dfrac{\partial}{\partial c_{m-1}}}_{j - l_m \text{ times}} S'\Big](1) & \text{if } j \ge l_m. \end{cases}$$

Furthermore, the Taylor expansion (21) shows that the above derivatives specify S uniquely therefore, in order to prove that some coloring is such as claimed by Theorem 11 it is enough to show that (28)–(29) hold true if S is replaced by $\mathbb{E}[T_\epsilon]$ and—by Inductive hypothesis 13—if S' is replaced by $\mathbb{E}[T_{\epsilon'}]$, namely

(30)
$$\left[\frac{\partial}{\partial x_j} \cdots \frac{\partial}{\partial x_1} \mathbb{E}[T_\epsilon]\right](1) = 0 \qquad \text{if } (x_1, \dots, x_j) \neq (c_m, \cdots, c_m),$$

$$\Big[\underbrace{\frac{\partial}{\partial c_m}\cdots\frac{\partial}{\partial c_m}}_{j\text{ times}}\mathbb{E}[T_\epsilon]\Big](1)= \tag{31}$$

$$\begin{cases} 0 & \text{if } j<l_m,\\ (-1)^j\Big[\underbrace{\frac{\partial}{\partial c_{m-1}}\cdots\frac{\partial}{\partial c_{m-1}}}_{j-l_m\text{ times}}\mathbb{E}[T_{\epsilon'}]\Big](1) & \text{if } j\geq l_m. \end{cases}$$

This idea of proving Theorem 11 should not come as a surprise since basically the same idea appears in the proof of Theorem 10 presented in [Śni03]; namely it was proved there that

$$\Big[\frac{d^j}{dx^j}\mathbb{E}[T_\epsilon]\Big](1)=\begin{cases}0 & \text{if } j<l_m,\\ (-1)^j\Big[\frac{d^{j-l_m}}{dx^{j-l_m}}\mathbb{E}[T_{\epsilon'}]\Big](1) & \text{if } j\geq l_m.\end{cases} \tag{32}$$

with the only difference that here $\mathbb{E}[T_\epsilon]\in\mathbb{R}[x]$ is just a polynomial and the derivatives are the usual derivatives.

In the following we are going to analyze the analytic proof of (32) presented in [Śni03] and find its ramifications in our more general context.

5.3. **Orders of derivatives.** The following lemma was critical in the proof of (32) in [Śni03].

Analytic lemma 14. *Let* $\epsilon=(\epsilon_1,\dots,\epsilon_{2k})$ *be a Catalan sequence. Then*

$$\frac{d^k}{dx^k}\mathbb{E}_{T_\epsilon}=(-1)^k,$$

where $\mathbb{E}_{T_\epsilon}\in\mathbb{R}[x]$ *is the usual polynomial in one variable as defined in* (3). *In the light of* (8) *it can be equivalently stated that*

$$\frac{d^k}{dx^k}T_\epsilon=(-1)^k\cdot(\textit{trivial tree consisting only of the root}), \tag{33}$$

where the derivative of trees should be understood as in (7).

We are going to find an analogue of the combinatorial identity (33) in which the robust derivative (7) would be replaced by a more refined derivative (13). We will do it by labeling the vertices in such a way that the derivatives of the form $\frac{\partial}{\partial x_k}\cdots\frac{\partial}{\partial x_1}T_\epsilon$ would have a particularly simple structure for any $x_1,\dots,x_l\in L$. This labeling will turn out to be the one required by Theorem 11.

Applying $\frac{d^k}{dx^k}$ to a tree is a sequential removing of k edges in all possible ways. In order to keep track of all such ways we use the notion of the *order of derivatives*.

Definition 15. $\Delta = (x_1, \dots, x_n)$ is an *order of the derivatives* of a tree T, when $x_1, \dots, x_n$ are different vertices of T (all different from the root) and x_k is a neighbor of the root in $\frac{\partial}{\partial x_{k-1}} \dots \frac{\partial}{\partial x_1} T$. In this case we write $\partial_\Delta T = \frac{\partial}{\partial x_n} \dots \frac{\partial}{\partial x_1} T$.

This name *order of derivatives* is motivated by the fact that

$$\left(\sum_{x \in L} \frac{\partial}{\partial x} \right)^n T = \sum_{\Delta = (x_1, \dots, x_n)} \partial_\Delta T$$

and so we may view Δ as an order of removing vertices from the tree.

Since all the vertices have different labels we sometimes refer to Δ as tuple of labels. We are mainly interested in the case when Δ consists of all vertices different from the root; in this case we call it total order of derivatives. Also we will write $x_i <_\Delta x_j$ if $i < j$; in other words the derivative $\frac{\partial}{\partial x_i}$ is applied in ∂_Δ before the derivative $\frac{\partial}{\partial x_j}$.

5.4. **Orders of derivatives and involutions on trees.** A careful analysis (which can be found in Section 6) shows that the proof of the Analytic lemma 14 presented in [Śni03] is based on finding cancellations between all summands contributing to (33). In fact, these cancellations arise from some implicit pairing between all possible orders of derivatives. The latter statement is formalized in the following lemma.

Lemma 16. *Let a Catalan sequence ϵ be fixed. Let us consider pairs (σ, Δ) where σ is a non-crossing pairing compatible with ϵ and Δ is a total order of derivatives on T_σ. If we exclude the case when σ is the Catalan pairing and Δ is the preorder, then there is an explicit involution f without fix-points on the rest of those pairs such that*

$$\big[f(\sigma_1, \Delta_1) = (\sigma_2, \Delta_2) \big] \text{ implies } \big[\partial_{\Delta_1} T_{\sigma_1} = -\partial_{\Delta_2} T_{\sigma_2} \big]. \tag{34}$$

Also, if $\Delta_1 = (x_1^{(1)}, \dots, x_n^{(1)})$ is such that for some k the vertices $x_1^{(1)}, \dots, x_k^{(1)}$ satisfy

- $x_1^{(1)} \lhd x_2^{(1)} \lhd \dots \lhd x_k^{(1)}$,
- $x_1^{(i)} \succ r$ *for* $i = 1, \dots, k$

then the same applies to $\Delta_2 = (x_1^{(2)}, \dots, x_n^{(2)})$, namely

- $x_1^{(2)} \lhd x_2^{(2)} \lhd \dots \lhd x_k^{(2)}$,
- $x_i^{(2)} \succ r$ *for* $i = 1, \dots, k$.

The explicit form of the pairing f will be constructed in Section 6 where we will also prove that it fulfills the above properties.

Any pair (T_σ, Δ), where Δ is a total order of derivatives on T_σ will be called a configuration.

5.5. **Trees with orders of derivatives versus trees with total orders.** We encounter here a major difficulty, namely the labeling wanted in Theorem 11 is a labeling of the vertices of trees T_σ equipped with compatible total orders while the analytic proof of [Śni03] and Lemma 16 suggest that we should rather work with configurations (T_σ, Δ). As one can easily see, these two notions are quite different and in the following we will have to reconcile them.

In order to do this let us have a look on the following problem. Let an oriented tree T be fixed. *Can we associate some canonical order of derivatives* $\Delta = (x_1, \dots, x_k)$ *on* T *to a given total order* $<$ *on the vertices of* T*?* Let $a_1, \dots, a_m \prec r$ and $b_1, \dots, b_n \succ r$ be the direct neighbors of the root r; we may assume that their numbering was chosen in such a way that $a_1 < \dots < a_m < r < b_1 < \dots < b_n$. In the extreme case when $k = 1$ and the tree T has no other vertices than $a_1, \dots, a_m, r, b_1, \dots, b_n$ we may think that the total order $<$ gives to the set of the vertices a structure of a chain, cf Fig. 2. In this chain the root r has (at most) two direct neighbors which could be differentiated, namely a_m and b_1. Therefore it seems reasonable to say that an order of derivatives $\Delta = (x_1)$ is compatible with the total order $<$ if $x_1 \in \{a_m, b_1\}$. The above discussion motivates heuristically the following definition.

Definition 17. Let T be an oriented tree, $<$ be a total order on the vertices of T which is compatible with the orientations of the edges and let $\Delta = (x_1, \dots, x_k)$ be an order of derivatives. We say that $<$ and Δ are compatible if for every $1 \le l \le k$ one of the following conditions holds true:

- x_l is the biggest element (with respect to $<$) of the set $\{x \in T_l : x \prec_{T_l} r\}$,
- x_l is the smallest element (with respect to $<$) of the set $\{x \in T_l : r \prec_{T_l} x\}$,

where the tree T_l is given by $T_l = \frac{\partial}{\partial x_{l-1}} \cdots \frac{\partial}{\partial x_1} T$.

We are going to investigate which information is preserved when we replace a total linear order by one of the corresponding total orders of derivatives. The answer to this problem will be given in Theorem 20 below.

Definition 18. Let $x \neq r$ be a vertex of an oriented tree $T \in \mathcal{T}$ and let $(x_0, \dots, x_n)$ be the shortest path connecting the root $r = x_0$ and $x = x_n$. Let $1 \le i \le n-1$ be the biggest index such that $x_{i-1} \prec x_i \succ x_{i+1}$ or $x_{i-1} \succ x_i \prec x_{i+1}$. If such an index exists we say that x_i is *the last bend* of x. We say that vertices $x, y \in T$ are in the same layer if one of the following conditions holds true:

- x and y have the same last bend;

- $x, y \prec r$ or $x, y \succ r$.

Definition 19. Let a tree T be given. Let Δ_1 and Δ_2 be total orders of derivatives. We say that $\Delta_1 \sim_d \Delta_2$ if $x <_{\Delta_1} y \iff x <_{\Delta_2} y$ holds for all x, y which are in the same layer.

Let $<_1, <_2$ be total linear orders on the vertices of T compatible with the orientations of the edges. We say that $<_1 \sim_o <_2$ if $x <_1 y \iff x <_2 y$ holds for all x, y which are in the same layer.

Theorem 20. *The notion of compatibility (Definition 17) provides a bijection between the classes of the equivalence relation $\sim_o$ and the classes of the equivalence relation $\sim_d$.*

Proof. The proof is immediate. □

Let some equivalence class c of the equivalence relation $\sim_o$ be given (hence it is an equivalence class of the relation $\sim_d$); we define

$$\mathbb{E}[T, c] = \sum_{<\in c} T_< \in \mathcal{R}[r],$$

where $T_< \in \mathcal{R}[r]$ denotes the chain defined by the linear order $<$. The same definition makes sense if c is replaced by an equivalence class of $\sim_d$.

Theorem 21. *Let c be an equivalence class of $\sim_d$ and $\Delta = (x_1, \ldots, x_m)$ be an order of derivatives of the tree T. If Δ is not a prefix of any element of c then*

$$\partial_\Delta \mathbb{E}[T, c] = 0.$$

If Δ is a prefix of a total order of derivatives $(x_1, \ldots, x_n) \in c$ then

$$\partial_\Delta \mathbb{E}[T, c] = \mathbb{E}\Big(\partial_\Delta T, \big[(x_{m+1}, \ldots, x_n)\big]_{\sim_d} \Big).$$

Proof. Assume for simplicity that Δ is a total order of derivatives. We consider any linear order $<$ which belongs to the class c. We consider a graph T' with the same set of the vertices as T and for each pair of vertices $v < w$ we draw an arrow from w to v if one of the following conditions hold true:

- vertices v and w are in the same layer and there is no vertex z in the same layer which fulfills $v < z < w$;
- one of the vertices (let us denote it by p) is the last bend of the other (let us denote it by q) and there is no vertex z in the same layer as q which fulfills $v < z < w$.

It is easy to check that the above definition does not depend on the choice of $<$ and that the resulting graph T' is a tree. Furthermore, each total linear

order $<$ is compatible with the orientations of the edges of T' if and only if $<$ belongs to c. It follows that

$$\mathbb{E}[T, c] = \mathbb{E}[T'].$$

Furthermore, any total order of derivatives Δ belongs to the equivalence class specified by c if and only if Δ is an order of derivatives on T'. Therefore

$$\partial_\Delta \mathbb{E}[T, c] = \mathbb{E}[\partial_\Delta T']$$

which finishes the proof.

The case when Δ is not necessarily total follows in a similar way. □

5.6. **Towards the labeling.** Our ultimate goal is to find some special labeling (coloring) of the vertices of the trees $(T_\sigma, <)$ equipped with total orderings; in order to do this we shall follow the following two principles:

(1) for pairs $(T_\sigma, <)$ from the same equivalence class of $\sim_o$ the labeling of the vertices of T_σ should be the same (our motivation is Theorem 21 since this requirement would imply that for any configuration (T_σ, Δ) the coloring of the vertices of T_σ is well-defined);

(2) for any two configurations $\left(T_{\sigma_i}, (x_1^{(i)}, \dots, x_n^{(i)})\right)$, $i \in \{1, 2\}$, which are paired by Lemma 16 we require that their colorings should be compatible in a sense that the color of $x_k^{(1)}$ in tree T_{σ_1} should coincide with the color of $x_k^{(2)}$ in tree T_{σ_2} for any value of $k \in \{1, \dots, n\}$.

As we shall see in the following, these conditions are quite restrictive and there are not too many such labelings.

Let us consider a graph $\mathbb{G}$ with the set of vertices equal to the set of pairs $(T_\sigma, [\Delta]_{\sim_d})$ or, equivalently, the set of pairs $(T_\sigma, [<]_{\sim_o})$. If

$$f(T_\sigma, \Delta) = (T_{\sigma'}, \Delta') \quad \text{and} \quad \left|\{v \in T_\sigma : v \succ r\}\right| > \left|\{v \in T_{\sigma'} : v \succ r\}\right|$$

then we put a directed edge $\left((T_\sigma, [\Delta]_\sim), (T_{\sigma'}, [\Delta']_\sim)\right)$ between the appropriate equivalence classes. We denote the connected component of the vertex $(T_\sigma, [\Delta]_{\sim_d}) \in \mathbb{G}$ by $\mathbb{G}(T_\sigma, [\Delta]_{\sim_d})$ or simply $\mathbb{G}(T_\sigma, \Delta)$.

Proposition 22. *Assume that ϵ is a Catalan sequence. Every vertex of $\mathbb{G}$ has at most one outgoing edge and $\mathbb{G}$ is acyclic therefore every component has a* sink*—the only vertex with no outgoing edges.*

Configuration (T_σ, Δ) with $\Delta = (x_1, \dots, x_n)$ corresponds to a sink $(T_\sigma, [\Delta]_{\sim_d})$ if and only if there exists a number k with a property that $\{x_1, \dots, x_k\} = \{v \in T_\sigma : v \succ r\}$ and the order of the elements $(x_1, \dots, x_k)$ coincides with the preorder.

We postpone the proof to Section 6.

Theorem 23. *We assume that ϵ is a Catalan sequence. Let $(T_\sigma, [\Delta]_{\sim_d})$ be a sink and let some coloring of the vertices of T_σ be given (respectively, let some coloring of the vertices of all sinks be given). Then there is a unique way of extending this coloring to the vertices of the trees $(T_{\sigma'}, \Delta')$ (or, equivalently, trees $(T_{\sigma'}, <')$) which contribute to $\mathbb{G}(T_\sigma, \Delta)$ (respectively, to all such trees) so that conditions (1), (2) from the beginning of Section 5.6 are fulfilled.*

Proof. Proposition 22 shows that there is a unique path in the graph $\mathbb{G}$ which connects any vertex with the sink. On the other hand, requirement (2) from the beginning of Section 5.6 shows that if the vertices of $\mathbb{G}$ corresponding to the trees (T_{σ_1}, Δ_1), (T_{σ_2}, Δ_2) are connected by an edge then the coloring of vertices of (T_{σ_1}, Δ_1) uniquely determines the coloring of the vertices of (T_{σ_2}, Δ_2) which finishes the proof. □

Let a coloring of the vertices of all trees $(T_\sigma, <)$ be given as above. We consider the element

$$\mathbb{E}[T_\epsilon] = \sum_{(T_\sigma, <)} (T_\sigma, <) \in \mathcal{R}[r], \tag{35}$$

where each summand $(T_\sigma, <)$ is identified with the corresponding chain of the colors of the vertices of T_σ. The following theorem shows that thanks to this coloring the derivatives of $\mathbb{E}[T_\epsilon]$ have a particularly simple structure.

Theorem 24. *Assume that ϵ is a Catalan sequence. Then for any colors $d_1, \dots, d_k$*

$$\frac{\partial}{\partial d_k} \cdots \frac{\partial}{\partial d_1} \mathbb{E}[T_\epsilon] = \sum_{(T_\sigma, [\Delta]_{\sim_d})} \mathbb{E}\left[\frac{\partial}{\partial x_k} \cdots \frac{\partial}{\partial x_1} (T_\sigma, \Delta) \right], \tag{36}$$

where the symbol (T_σ, Δ) on the right-hand side denotes the tree T_σ with the coloring of the vertices specified by (T_σ, Δ) as in Theorem 24; the sum runs over equivalence classes $(T_\sigma, [\Delta]_{\sim_d})$ for which there exists a representative $\Delta = (x_1, \dots, x_n)$ with the following properties:

- *the colors of the vertices $(x_1, \dots, x_k)$ of the tree (T_σ, Δ) are equal to $(d_1, \dots, d_k)$;*
- *all edges removed from T_σ by $\frac{\partial}{\partial x_k} \cdots \frac{\partial}{\partial x_1}$ are oriented towards the root;*
- *all edges removed from T_σ by $\frac{\partial}{\partial x_k} \cdots \frac{\partial}{\partial x_1}$ are removed in the order which coincides with the preorder.*

Proof. We may group the summands on the right-hand side of (35) according to the equivalence classes of $\sim_d$ and apply Theorem 21 therefore

$$\frac{\partial}{\partial d_k}\cdots\frac{\partial}{\partial d_1}\mathbb{E}[T_\epsilon] = \sum_{(T_\sigma,[\Delta]_{\sim_d})} \mathbb{E}\left[\frac{\partial}{\partial x_k}\cdots\frac{\partial}{\partial x_1}(T_\sigma,\Delta)\right],$$

where the sum on the right-hand side runs over all $(T_\sigma,[\Delta]_{\sim_d})$, $\Delta = (x_1,\ldots,x_n)$ such that the colors of the vertices $(x_1,\ldots,x_k)$ of the tree (T_σ,Δ) are equal to $(d_1,\ldots,d_k)$.

Let us disregard for a moment all vertices of the trees other than $x_1,\ldots,x_k$; we denote such a truncated tree by $\tilde{T}$. The involution f from Lemma 16 can be applied to the set of such truncated trees; the contribution of all paired trees cancel and the only remaining trees are as prescribed in the formulation of the theorem.

For completeness of this proof one should check that that the involution f applied to a the truncated tree $(\tilde{T},(x_1,\ldots,x_k))$ gives the truncation of $f(T,\Delta)$. This, however, will become obvious in Section 6 when the explicit form of f will be given. □

5.7. **Proof of the main result.** In fact, we shall prove Theorem 11 together with the following additional inductive hypothesis.

Additional inductive hypothesis 25. *If (T_σ,Δ) is a configuration with $\Delta = (x_1,\ldots,x_n)$ and p is such that all edges removed by the derivative $\frac{\partial}{\partial x_p}\cdots\frac{\partial}{\partial x_1}T_\sigma$ are oriented towards the root and they are removed in the order which coincides with the preorder then the vertices $x_1,\ldots,x_p$ are painted by color c_m.*

Proof of Theorem 11. As we already pointed out in Section 5.1, it is enough to find a coloring with a property that equations (30), (31) are fulfilled.

In view of Theorem 23 it is enough to define the coloring on the sinks of the graph $\mathbb{G}$. Equation (36) shows that

$$\left(\frac{\partial}{\partial d_k}\cdots\frac{\partial}{\partial d_1}\mathbb{E}[T_\epsilon]\right)(1) = \sum_{(T_\sigma,[\Delta]_{\sim_d})} \mathbb{E}\left[\frac{\partial}{\partial x_k}\cdots\frac{\partial}{\partial x_1}(T_\sigma,\Delta)\right](1), \tag{37}$$

where the sum runs over equivalence classes $(T_\sigma,[\Delta]_{\sim d})$ for which there exists a representative $\Delta = (x_1,\ldots,x_n)$ with a property that $\{x_1,\ldots,x_k\} = \{v\in T_\sigma : v \succ r\}$ and which fulfills the conditions from Theorem 24. In other words: $(T_\sigma,[\Delta]_{\sim_d})$ contributes to the above sum if and only if $(T_\sigma,[\Delta]_{\sim_d})$ corresponds to a sink in $\mathbb{G}$ for which k is as prescribed in Proposition 22.

Let us fix some sink $(T_\sigma,[\Delta]_{\sim_d})$; we can always assume that $\Delta = (x_1,\ldots,x_n)$ is as specified in Proposition 22 and that k is as above. Each of the edges of T_σ arises from a pair of the edges of the polygonal graph G_ϵ; let

us unglue the edges which are removed by the derivative $\frac{\partial}{\partial x_k}\cdots\frac{\partial}{\partial x_1}$ and let us decorate these edges. The resulting graph is a polygon with some trees attached or, in other words, it is the quotient graph $T_{\sigma'}$ where the partial pairing σ' is subset of the pairing σ. Among unglued edges there must be the edges of G_ϵ which correspond to the l_i initial and the l_i final elements of ϵ; let us remove these $2l_i$ edges. The resulting graph $T_{\sigma''}$ is a quotient graph of the polygonal graph $G_{\epsilon'}$. We can view $T_{\sigma''}$ as some polygonal graph G_δ with some trees attached. We glue the edges of G_δ by the Catalan pairing, we denote the resulting tree by $T_{\sigma'''}$. This tree has $k-l_i$ decorated edges which we denote by $(y_1,\dots,y_{k-l_i})$, in the order given by the preorder; we denote by $\Delta'=(y_1,\dots,y_{k-l_i},x_{k+1},x_{k+2},\dots,x_n)$ an order of derivatives on $T_{\sigma'''}$.

Now we are ready to define the coloring of the vertices of the tree T_σ: we paint the vertices $x_1,\dots,x_k$ with color c_m; all other vertices we paint with the same colors as the corresponding vertices in the tree $(T_{\sigma'''},\Delta')$ (this coloring is given by the inductive hypothesis).

In order to show that this coloring indeed fulfills (30) we use Eq. (37). Since by the construction of the coloring all vertices in the set $\{x : x \succ r\}$ of the sink are colored by color c_m therefore there is no summand which contributes to the right-hand side of (37) which finishes the proof of (30).

We will prove now that (31) holds true. In order to get a non-zero value in 1 of the right-hand side of (37) one has to remove by derivatives all vertices $\{x : x \succ r\}$. Since there are at least l_m such vertices therefore the first part of (31) follows.

For the second part of (31) note that by Additional inductive hypothesis 25 vertices $y_1,\dots,y_{k-l_i}$ have color c_{m-1} therefore $(T_{\sigma'''},\Delta')$ is one of the summands which contribute to (37) applied to the derivative $\underbrace{\frac{\partial}{\partial c_{m-1}}\cdots\frac{\partial}{\partial c_{m-1}}}_{j-l_m \text{ times}}\mathbb{E}[T_{\epsilon'}]$. The corresponding relation is one to one, that is given a summand contributing to the above sum we can find a sink such that it is its $(T_{\sigma'''},\Delta')$.

It remains now to prove that the coloring costructed above fulfills Additional inductive hypothesis 25. In order to do this assume that in (T,Δ) all edges removed by $\frac{\partial}{\partial x_p}\cdots\frac{\partial}{\partial x_1}T_\sigma$ are oriented towards the root and removed in the order coinciding with the preorder. By Lemma 16 the same happens in the corresponding sink (T',Δ') and by the construction of the coloring all vertices in the set $\{v : v \succ r\}$ removed in the sink are painted by color c_m which finishes the proof.

In this way we proved that the presented coloring has the required properties. One can check that this coloring coincides with the one presented in the paper [Śni06]. □

6. How to convert an analytic proof into involution f

In this section we will analyze the proof of Analytic lemma 14 presented in [Śni03] and we will show how the involution f can be constructed out of it.

6.1. **Sketch of proof of Analytic lemma 14.** The proof of Analytic lemma 14 presented in [Śni03] was based on the following observation. The left-hand side of (33) is a sum over all possible ways of choosing a quotient tree T_σ and then choosing the order of the derivatives $\frac{\partial}{\partial x_k}\cdots\frac{\partial}{\partial x_1}$. Let us concentrate on the last derivative $\frac{\partial}{\partial x_k}$ in the above product. This derivative removes the edge x_k of the tree T_σ; this edge of T_σ corresponds to a pair of edges in the polygonal graph G_ϵ. Since one of the ends of x_k is a leaf therefore the corresponding pair of edges e_i, e_{i+1} must be adjacent and have opposite orientations, i.e. $\epsilon_i + \epsilon_{i+1} = 0$. We denote by $(\epsilon)_i$ the sequence ϵ with elements $\epsilon_i, \epsilon_{i+1}$ corresponding to these edges removed. It is easy to see that the contribution to (33) of all summands for which the edge x_k is fixed is equal to $-\epsilon_i \frac{d^{k-1}}{dx^{k-1}} T_{(\epsilon)_i}$. In this way we proved that

$$\frac{d^k}{dx^k} T_\epsilon = \sum_{\substack{i:\\ \epsilon_i+\epsilon_{i+1}=0}} (-1)\epsilon_i \cdot \frac{d^{k-1}}{dx^{k-1}} T_{(\epsilon)_i}. \tag{38}$$

The assumption that ϵ is a Catalan sequence implies that each sequence $(\epsilon)_i$ is Catalan as well and the inductive hypothesis can be applied; it follows that

$$\frac{d^k}{dx^k} T_\epsilon = \sum_{\substack{i:\\ \epsilon_i+\epsilon_{i+1}=0}} (-1)\epsilon_i \cdot (-1)^{k-1}.$$

Now it is enough to notice that if $i_1 < \cdots < i_l$ are all indices such that $(\epsilon_{i_j}, \epsilon_{i_j+1}) = (1,-1)$ and $i'_1 < \cdots < i'_{l'}$ are all indices such that $(\epsilon_{i'_j}, \epsilon_{i'_j+1}) = (-1,1)$ then the sequences (i_j) and (i'_j) are interlacing: $i_1 < i'_1 < i_2 < \cdots < i'_{l-1} < i_l$ therefore

$$\frac{d^k}{dx^k} T_\epsilon = \sum_{\substack{i:\\ \epsilon_i+\epsilon_{i+1}=0}} \epsilon_i \cdot (-1)^k = \big[l\cdot(+1) + (l-1)\cdot(-1)\big](-1)^k = (-1)^k,$$

which finishes the proof.

6.2. **How to find the involution in Lemma 16.** We are going to find the involution as in Lemma 16 by following the proof presented in Section 6.1.

Firstly, since the proof in Section 6.1 is inductive, our construction of the involution f will be inductive as well. For the shortest possible Catalan sequence $\epsilon = (1,-1)$ there is only one pairing σ (which is the Catalan pairing) and only one total order of derivatives Δ (which coincides with preorder $\lhd$) therefore there is nothing to pair and $f = \emptyset$.

If ϵ consists of at least four elements, the proof of (38) suggests that we should group all pairs

$$\big(T_\sigma, \Delta = (x_1, \dots, x_k)\big) \tag{39}$$

into classes according to the value of the edge x_k or, in other words, according to the pair of edges (e_i, e_{i+1}). Similarly as in Section 6.1 the set of pairs (39) for a fixed value of i can be identified with the set of pairs $\big(\sigma', (x_1, \dots, x_{k-1})\big)$ which contribute to the the derivative $\frac{d^{k-1}}{dx^{k-1}} T_{(\epsilon)_i}$. It follows that for each group of pairs (T_σ, Δ) corresponding to a given value of i (such that $\epsilon_i + \epsilon_{i+1} = 0$) we can construct a pairing f inductively. Nevertheless, for each value of i there is one pair (T_σ, Δ) which remains unpaired and in order to finish the construction of f we should find some pairing between these remaining elements. The requirement (34) implies that that an index i for which $(\epsilon_i, \epsilon_{i+1}) = (1,-1)$ should be paired with an index i' for which $(\epsilon_i, \epsilon_{i+1}) = (-1,1)$.

As we already mentioned in Section 6.1, if $i_1 < \dots < i_l$ are all indices such that $(\epsilon_{i_j}, \epsilon_{i_j+1}) = (1,-1)$ and $i'_1 < \dots < i'_{l-1}$ are all indices such that $(\epsilon_{i'_j}, \epsilon_{i'_j+1}) = (-1,1)$ then the sequences (i_j) and (i'_j) are interlacing: $i_1 < i'_1 < i_2 < \dots < i'_{l-1} < i_l$. We have a relative freedom in choosing the pairing between the elements of the set $\{i_1, \dots, i_l\}$ and $\{i'_1, \dots, i'_{l-1}\}$ and we decided to choose a fairly natural one: $i_1 \leftrightarrow i'_1, \dots, i_{l-1} \leftrightarrow i'_{l-1}$ with the index i_l unpaired.

The above inductive procedure determines the involution f claimed in Lemma 16 uniquely, nevertheless this description is quite implicit and we will present its explicit form in the following section.

6.3. **Explicit form of the involution f.**

Lemma 26. *The pair (T_σ, Δ) for which σ is the Catalan pairing and Δ is the preorder $\lhd$ is the unique pair which is unpaired by the involution f described in Section 6.2.*

Proof. The element (39) unpaired by f must belong to the class considered in Section 6.2 corresponding to the only unpaired index i_l for which $(\epsilon_{i_l}, \epsilon_{i_l+1}) = (1,-1)$ therefore the edge x_k must be oriented towards the

root. Also the pair

$$\left(T'_\sigma, (x_1, \ldots, x_{k-1})\right) \tag{40}$$

corresponding to the sequence $(\epsilon)_{i_l}$ must be unpaired by f; by iterating this argument it follows that all edges in the tree T_σ are oriented towards the root hence σ is the Catalan pairing.

Since the only element unpaired by f must belong to the class considered in Section 6.2 corresponding to the only unpaired index i_l therefore x_k is the last edge with respect to the preorder $\lhd$ in the tree T_σ. By passing to (40) and iterating the argument we see that Δ coincides with $\lhd$. □

Let a pair (T_σ, Δ) be given, we shall compute explicitly the value of $f(\sigma, \Delta)$. It is easy to see that the algorithm described implicitly in Section 6.2 looks for the smallest value p for which the pairing f is well-defined for $(\sigma', \frac{\partial}{\partial x_p} \cdots \frac{\partial}{\partial x_1})$ (where σ' is a pairing for the sequence ϵ with the elements corresponding to the edges $x_{p+1}, x_{p+2}, \ldots$ removed). Lemma 26 shows that p is the smallest value for which one of the following conditions hold:

(1) the order of the vertices in the sequence $(x_1, \ldots, x_p)$ does not coincide with the preorder;
(2) edge removed by the last derivative in the product $\frac{\partial}{\partial x_p} \cdots \frac{\partial}{\partial x_1}$ is not oriented towards the root.

We shall concentrate in the following on the case (1). Let us traverse the plane tree T_σ truncated to the vertices $r, x_1, \ldots, x_p$ starting from the vertex x_p. We denote by (x_m, x_k) the first edge we traverse in the direction opposite to its orientation and by (x_l, x_k) the previous edge, cf Figure 9.

The edge of T_σ removed by the last derivative $\frac{\partial}{\partial x_p}$ in the product $\frac{\partial}{\partial x_p} \cdots \frac{\partial}{\partial x_1}$ corresponds to a pair of edges $(\epsilon_{i_j}, \epsilon_{i_j+1})$ of the polygonal graph G_ϵ. These two edges were paired with $(\epsilon_{i'_j}, \epsilon_{i'_j+1})$ which correspond to one of the half-edges constituting (x_l, x_k) and to one of the half edges constituting (x_m, x_k). The pairing f is defined in the following, seemingly complicated way: we unglue all edges appearing in the tree T_σ truncated to the vertices $r, x_1, \ldots, x_p$, we glue together one of the half-edges (x_l, x_k) to one of the half edges (x_m, x_k) and then we glue all remaining unglued edges by the Catalan pairing. Notice, however, that this operation can be equivalently described in a much simpler way: we unglue two edges of T_σ, namely (x_l, x_k) and (x_m, x_k), cf Figure 10 and we reglue them in a different way, cf Figure 11. The resulting tree $T_{\sigma'}$ is the wanted tree such that $f(T_\sigma, \Delta) = (T_{\sigma'}, \Delta')$.

In order to describe the order of derivatives Δ' it will be convenient to label the vertices of $T_{\sigma'}$ with the same labels as the vertices of T_σ, namely $x_1, x_2, \ldots$. Question arises therefore: how to label the vertices of $T_{\sigma'}$ in

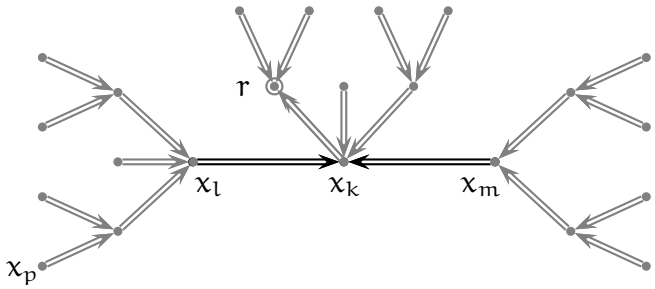

FIGURE 9. Tree for which the order of the vertices given by Δ does not coincide with the preorder. The indices fulfill $k < l < m < p$. Only the vertices $r, x_1, \dots, x_p$ were shown.

such a way that $\Delta' = (x_1, x_2, \dots)$. There is a seemingly complicated way of describing this labeling: firstly, we need to bother only with the part of the tree T_σ which consists of the vertices $r, x_1, \dots, x_p$ and the corresponding part of the tree $T_{\sigma'}$ (we do not change the gluings of any other edges and the labels given to other vertices remain the same in $T_{\sigma'}$). Secondly, in the process of calculating the derivative $\frac{\partial}{\partial x_p} \cdots \frac{\partial}{\partial x_1} T_{\sigma'}$ the first $p-1$ derivatives should remove the edges oriented towards the root in the order given by the preorder and the derivative $\frac{\partial}{\partial x_p}$ should remove the only edge which is oriented opposite than towards the root. Notice, however, that this labeling can be described in an equivalent, simpler way, by saying that all vertices of T_σ except from x_k, x_l, x_m, x_p keep their labels in the tree $T_{\sigma'}$ and the labels of the other vertices can be read by comparing the Figure 9 and Figure 11.

For simplicity, in the above discussion we considered only the case when $x_l \neq x_p$; otherwise only a minor correction is necessary, namely Figure 9 must be replaced by Figure 12 and Figure 11 by Figure 13.

In this way our analysis of case (1) is finished. Notice that in this case $\left|\{v \in T_\sigma : v \succ r\}\right| > \left|\{v \in T_{\sigma'} : v \succ r\}\right|$ therefore in the graph $\mathbb{G}$ there is an oriented edge pointing from the vertex correspondning to the equivalence class $(T_\sigma, [\Delta]_{\sim_d})$ to the vertex corresponding to the equivalence class $(T_{\sigma'}, [\Delta']_{\sim d})$.

In the case (2) involution f is just the inverse of the map f described above for the case (1); in this case the edge in the graph $\mathbb{G}$ is oriented in the opposite direction as in the case (1).

6.4. **Proof of Proposition 22.**

Proof of Proposition 22. Any configurations (T_σ, Δ_1), (T_σ, Δ_2) which contribute to the same vertex of $\mathbb{G}$ can be transformed into each other by repeatedly interchanging the order of adjacent derivatives which remove an

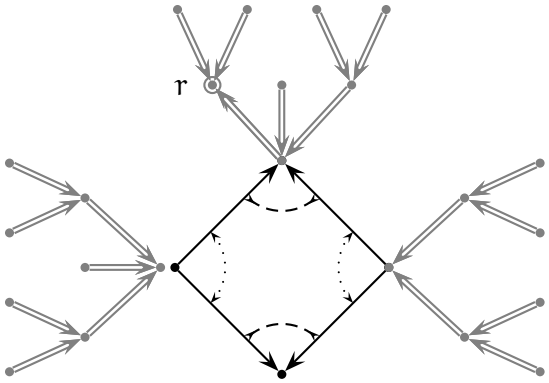

FIGURE 10. The tree from Figure 9 after ungluing the edges (x_l, x_k), (x_m, x_k).

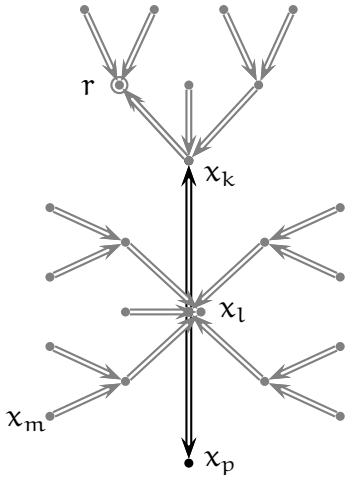

FIGURE 11. The tree from Figure 9 after regluing the edges (x_l, x_k) and (x_m, x_k) in a different way. Notice the change of the labels of the vertices x_k, x_l, x_m, x_p.

edge oriented towards the root and an edge oriented opposite to towards the root. If these configurations give rise to outgoing edges in the graph $\mathbb{G}$ it follows that the case (1) holds true for both (T_σ, Δ_1) and (T_σ, Δ_2). One can easily see that in both cases the procedure described in Section 6.3 unglues and reglues the same two edges hence the resulting configurations $f(T_\sigma, \Delta_1)$ and $f(T_\sigma, \Delta_2)$ belong to the same equivalence class hence correspond to the same vertex of $\mathbb{G}$. This shows that every vertex of $\mathbb{G}$ has at most one outgoing edge.

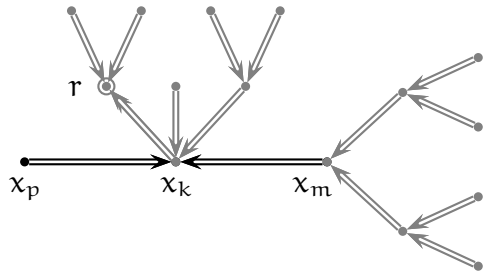

FIGURE 12. Tree for which the order of the vertices given by Δ does not coincide with the preorder, the case when $x_l = x_p$.

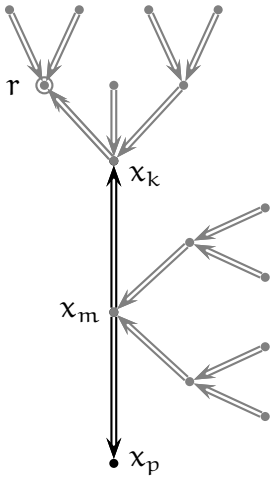

FIGURE 13. The tree from Figure 12 after regluing the edges (x_l, x_k) and (x_m, x_k) in a different way. Notice the change of the labels of the vertices x_k, x_m, x_p.

If the vertices corresponding to the configurations (T_σ, Δ), $(T_{\sigma'}, \Delta')$ are connected by an oriented edge then

$$\left|\{x \in T_\sigma : x \succ r\}\right| > \left|\{x \in T_{\sigma'} : x \succ r\}\right|$$

therefore there are no oriented cycles in $\mathbb{G}$.

The second part of Proposition 22 follows easily from the description of map f in Section 6.3. □
